

Bundle-theoretic methods in data science

Jose Perea

Northeastern University

Many tasks in data science, including distributed modeling, dimensionality reduction, data alignment and coordinatization, can be phrased as local-to-global inference problems with well-defined topological obstructions. The goal of this talk is to describe several of these constructions, their applications to specific machine learning problems, and the emergent theoretical/algorithmic challenges in geometric and topological data analysis.

In Special Invited Talks at the Mathematical Congress of the Americas 2025.
