

A counterexample to Nash's question on resolution of singularities

Daniel Duarte

CCM-UNAM

The Nash transformation of an algebraic variety is a modification that replaces singular points by limits of tangent spaces. It was proposed to resolve singularities by iterating the Nash transformation. In this talk we present a counterexample to this question. This is a joint work with Federico Castillo, Maximiliano Leyton and Álvaro Liendo.

In Special Session 26 on Foliations and Singularities at the Mathematical Congress of the Americas 2025.
