

66- Generalized Front Propagation for Stochastic Spatial Models

Jessica Lin

McGill University

In this talk, I will present a general framework which can be used to analyze the scaling limits of various stochastic spatial "population" models. Such models include ternary Branching Brownian motion subject to majority voting and several examples of interacting particle systems motivated by biology. The approach is based on moment duality and a PDE methodology introduced by Barles and Souganidis, which can be used to study the asymptotic behaviour of rescaled reaction-diffusion equations. In the limit, the models exhibit phase separation with an evolving interface which is governed by a global-in-time, generalized notion of mean-curvature flow.

In Special Session 66 on Recent Developments in Interacting Particle Systems and their Applications at the Mathematical Congress of the Americas 2025.
